CERTIFICATE

This is to certify that the Study Report entitled “Impact of Streaming Behavior on Study Delay Among Students” has been carried out by Ancilla Fiona Dsouza (Register Number: RA2532271010013), a student of M.S. FinTech, Department of Economics, Faculty of Science and Humanities,
SRM Institute of Science and Technology, Kattankulathur, under my guidance.

This study report is being submitted in partial fulfilment of the requirements for the award of the degree of Master of Science in Financial Technology (M.S. FinTech) during May 2026 - Modular 4. The work embodied in this report is original and has not been submitted earlier for the award of any degree or diploma of this or any other university.

PROJECT GUIDE

**Approved by
External Examiners**

ACKNOWLEDGEMENT

I would like to extend my sincere gratification to our **Head of Department, Dr. Gopi D**, for his continuous support, motivation, and for providing us with the necessary resources and opportunities to undertake this case study. His encouragement has been vital in enabling me to carry out this work successfully.

I would also like to express my heartfelt gratitude to **Dr. Sravaitri Chaudhuri** for her valuable guidance, constructive suggestions, and constant encouragement throughout the completion of this study. Their expertise and mentorship have been instrumental in shaping the direction of this study.

ABSTRACT

This study examines the impact of streaming behaviour on students' study delay during examination periods using a mixed-methods approach combining Binary Logistic Regression and qualitative thematic analysis. Primary data were collected from 115 students through a structured cross-sectional survey questionnaire. The quantitative analysis investigated the influence of behavioural factors such as streaming frequency, streaming time, over-watching behaviour, and age on students' probability of delaying academic activities during exams.

The Binary Logistic Regression results revealed that streaming time and over-watching behaviour were statistically significant predictors of study delay. In particular, over-watching behaviour substantially increased the likelihood of procrastination and ineffective study management during examination preparation. The model achieved an overall classification accuracy of 63.5% with an ROC-AUC score of 0.69, indicating satisfactory predictive performance. Multicollinearity diagnostics using Variance Inflation Factor (VIF) confirmed that the independent variables were free from severe multicollinearity issues.

The qualitative thematic analysis of 69 valid student responses further supported the quantitative findings by identifying dominant behavioural patterns such as distraction, loss of time control, prolonged streaming sessions, reduced concentration, and procrastination-related study delay. Many students reported that short planned study breaks frequently transformed into extended streaming sessions due to continuous content consumption and auto-play recommendations.

Overall, the findings suggest that excessive streaming behaviour negatively affects students' academic discipline, focus, and time management during examination periods. The study highlights the importance of behavioural self-regulation, controlled digital entertainment usage, and external supervision mechanisms in improving students' academic consistency during exams.

CHAPTER 1

INTRODUCTION

1.1 ABOUT THE DOMAIN

The contemporary media landscape has undergone a major transformation with the rapid growth of Over-the-Top (OTT) streaming platforms that deliver digital content directly through internet-enabled devices. Unlike traditional television broadcasting, streaming platforms provide users with greater flexibility in selecting content, viewing duration, and viewing schedules. Among students, platforms such as YouTube, Netflix, and other digital entertainment services have become important sources of relaxation, entertainment, and stress relief. As digital entertainment usage continues to increase among younger populations, understanding how streaming exposure influences students' academic discipline and time management has become increasingly relevant within modern educational environments.

1.2 BACKGROUND OF THE STUDY

The transition toward digital and hybrid learning models, accelerated by global events like the COVID-19 pandemic, has fundamentally altered how students interact with both educational resources and digital entertainment. While platforms such as YouTube and Netflix provide access to valuable informative content, they also offer a limitless library of distractions. Students often find themselves navigating a porous boundary between study periods and digital breaks. The immersive nature of modern streaming, supported by recommendation algorithms and autoplay features, has introduced the phenomenon of "binge-watching" as a social norm. As students increasingly rely on these platforms for stress relief, there is a growing need to investigate how the resulting behavioral patterns—specifically the inability to disengage from content—intersect with academic obligations during high-stakes examination periods.

1.3 PROBLEM STATEMENT

Academic success during examination periods depends heavily on disciplined time allocation, effective study planning, and consistent academic focus. However, the rapid growth of Over-the-Top (OTT) streaming platforms such as YouTube, Netflix, and other digital entertainment services has introduced a significant behavioural challenge among students during exam preparation periods.

Many students initially use streaming platforms as a form of short-term relaxation or stress relief during study breaks. However, the immersive nature of streaming platforms, supported by features such as auto-play recommendations, continuous content availability, and personalized entertainment algorithms, often encourages prolonged viewing behaviour beyond the student's original intention.

As a result, planned short-duration study breaks may gradually transform into extended streaming sessions, leading to overwatching behaviour, loss of time control, ineffective study scheduling, and eventual study delay during examinations.

Although previous studies have examined binge-watching behaviour and academic procrastination, limited empirical research has specifically analyzed streaming behaviour during examination preparation periods using an econometric framework.

Therefore, the present study seeks to examine how streaming-related behavioural factors contribute to students' study delay during examination periods using a Binary Logistic Regression approach.

1.4 NEED FOR THE PROJECT

There is a critical need to quantify the risk factors associated with digital procrastination to inform both student self-management and institutional support frameworks. Understanding the statistical significance of variables such as viewing time and overwatching allows for the development of targeted interventions rather than blanket restrictions. By identifying whether frequency or intensity is the primary driver of delay, researchers can suggest more effective digital wellness strategies. Furthermore, qualitative insights into student motivations provide a human context to statistical trends, revealing how stress and cognitive fatigue drive escapist behaviors. This project serves as a foundational study for designing educational environments that balance digital engagement with academic rigor, ultimately supporting the long-term well-being and professional readiness of the student body.

1.5 SCOPE OF THE PROJECT

The project encompasses a structured analytical workflow beginning with the collection of primary survey data from 115 students across different educational levels, including school-level, undergraduate, and postgraduate students. The scope of the study includes descriptive statistical analysis, correlation analysis, and the estimation of a Binary Logistic Regression model to identify

behavioural predictors of study delay among students. In addition, the study incorporates qualitative thematic analysis of open-ended survey responses to examine behavioural patterns associated with digital entertainment usage and academic procrastination during examination periods. The study specifically focuses on streaming-related activities during exam preparation intervals and their influence on students' academic discipline and study consistency.

1.6 OBJECTIVES OF THE PROJECT

The primary objective of this study is to analyze the impact of streaming behaviour on students' study discipline and time management during examination periods.

Specifically, the study aims:

- To examine the relationship between streaming frequency and students' likelihood of postponing academic activities during examinations.
- To analyze the impact of overwatching behaviour on study delay among students.
- To estimate the effect of streaming duration on students' academic time management using a Binary Logistic Regression model.
- To evaluate whether behavioural streaming patterns vary across different student age groups.
- To provide an econometric understanding of how streaming-related behavioural factors influence students' probability of delaying their studies during examination periods.

CHAPTER 2

LITERATURE REVIEW AND THEORETICAL BACKGROUND

2.1 THEORETICAL FRAMEWORK

The conceptual foundation of this study is built upon several key theories in social and behavioral science. The Theory of Planned Behavior (TPB) suggests that a student's intention to engage in streaming is driven by their attitude toward the activity as a stress reliever and their perceived level of behavioral control. However, when the immersive features of OTT platforms erode this control, a disconnect between intention and action occurs. Media Dependency Theory (MDT) posits that as students fulfill emotional and social needs through these platforms, their academic focus becomes secondary to digital engagement. Uses and Gratifications Theory (UGT) further explains that students are active agents who choose specific media to satisfy desires for relaxation or "escape," often resulting in a "substitution effect" where study time is replaced by leisure. Additionally, the study utilizes Temporal Motivation Theory (TMT), which mathematically expresses motivation as a balance between expectancy and value against impulsiveness and delay. In this model, the immediate reward of streaming frequently overpowers the delayed reward of high grades.

2.2 CONCEPTUAL FRAMEWORK

The conceptual framework of this study focuses on the relationship between streaming-related behavioural factors and students' study delay during examination periods. The study examines whether excessive streaming behaviour contributes to procrastination, ineffective time management, and delayed academic preparation.

The dependent variable of the study is:

- **Study Delay (Binary Variable)**
 - 1 = Delay in studies due to streaming behaviour
 - 0 = No delay in studies

The independent variables include:

- Streaming Frequency
- Streaming Time

- Overwatching Behaviour
- Age

The framework proposes that increased streaming exposure, excessive viewing duration, and loss of time control through overwatching behaviour increase the probability of students postponing academic tasks during examination periods.

Figure 1: Conceptual Framework

2.3 LITERATURE REVIEW

Previous scholarly studies have extensively examined the relationship between digital entertainment consumption, academic procrastination, and study delay among students. Existing literature mainly focuses on binge-watching behaviour, streaming platform usage, cognitive fatigue, and time-management difficulties associated with excessive digital media consumption.

Yolie and Hastuti (2024) examined the relationship between binge-watching habits and academic procrastination among university students using the Binge-Watching Addiction Questionnaire (BWAQ) and the Tuckman Procrastination Scale (TPS). The findings revealed a significant

positive relationship between streaming frequency and academic procrastination, indicating that students who engaged more frequently in binge-watching behaviour were more likely to delay academic tasks and lose focus during study activities.

Similarly, Kastiya and Sharma (2025) investigated the impact of binge-watching behaviour on academic procrastination among university students using a quantitative empirical approach. The study identified that increased streaming exposure negatively affected students' concentration, productivity, and study discipline. The researchers also observed that entertainment-driven streaming behaviour often overrode students' planned study schedules, contributing to ineffective time management.

Prakasha et al. (2024) examined students' usage of Over-the-Top (OTT) streaming platforms and their impact on academic productivity and socio-demographic characteristics. The findings suggested that excessive streaming usage reduced concentration levels, weakened time-management practices, and negatively affected academic efficiency. Streaming platforms were primarily used for entertainment and stress relief; however, prolonged usage created behavioural distractions that interfered with study consistency.

The Heliyon Study (2024) further explored the motivational determinants of binge-watching behaviour among university students. The study found that entertainment, escapism, and relaxation were major psychological drivers behind prolonged streaming behaviour. A significant positive relationship was observed between entertainment motivation and binge-watching frequency, suggesting that students often prioritize immediate entertainment gratification over long-term academic responsibilities.

In addition to streaming-related studies, Goulas and Megalokonomou (2018) examined the effects of exam scheduling on academic performance using administrative examination data from Greek high school students. The study found that examination timing, exam gaps, and extended examination periods significantly influenced cognitive fatigue and academic outcomes. Longer examination periods were associated with lower performance due to mental exhaustion, while later examinations sometimes improved performance through a "warm-up effect."

Similarly, Collis and Eggers (2022) studied the effects of restricting social media usage on students' wellbeing and academic performance through a randomized controlled trial approach. Their findings identified a substitution effect in which students shifted from social media to

alternative digital entertainment activities instead of reducing overall screen exposure, indicating persistent engagement in digital leisure behaviour.

Although previous studies provide important evidence regarding binge-watching behaviour, procrastination, and academic productivity, the majority of existing research primarily treats procrastination as a general behavioural phenomenon throughout the academic semester. Existing literature provides limited examination of streaming behaviour specifically during examination preparation periods, where students experience greater academic pressure and higher opportunity costs associated with time loss.

2.4 LITERATURE GAP

Despite increasing research on streaming behaviour and academic procrastination, several important gaps still exist. Most existing studies examine streaming or binge-watching as general entertainment behaviour, but limited research focuses specifically on students' streaming habits during examination preparation periods and their direct effect on study delay.

Previous studies also provide insufficient evidence on how different dimensions of streaming behaviour—such as streaming time, streaming frequency, and binge-watching behaviour—individually contribute to students' tendency to postpone or delay their studies during exams. The combined effect of these behavioural factors remains underexplored.

In addition, most research does not adequately compare how streaming-related study delay varies across different age groups of students, including school students, undergraduates, and postgraduates, leading to a gap in understanding age-wise behavioural differences.

Furthermore, although prior studies use basic statistical methods such as correlation and regression, limited research applies Binary Logistic Regression to estimate the probability of study delay based on streaming behaviour variables during examination periods.

Therefore, this study addresses these gaps by analyzing the impact of streaming time, streaming frequency, binge-watching behaviour, and age on students' study delay during examinations using a Binary Logistic Regression model.

2.5 SOCIAL AND EMOTIONAL DRIVERS OF DIGITAL PROCRASTINATION

Social and emotional factors also influence students' digital entertainment usage during examination periods. Many students use streaming platforms as a form of relaxation, stress relief, or temporary escape from academic pressure. However, prolonged streaming exposure may reduce concentration levels and interfere with planned study schedules, contributing to delayed academic preparation and reduced study consistency.

CHAPTER 3

DATASET DESCRIPTION

3.1 SOURCE OF DATA AND COLLECTION METHODOLOGY

The present study adopted a cross-sectional survey design to examine the impact of streaming behaviour on students' study delay during examination periods. Primary data was collected at a single point in time from students belonging to different educational levels and academic backgrounds.

A structured questionnaire was administered through Google Forms to collect the required data. The questionnaire consisted of both close-ended and open-ended questions related to students' streaming habits, streaming duration, overwatching behaviour, study delay, and academic focus during examinations. The use of a structured questionnaire ensured consistency in data collection across all respondents.

The survey was distributed through academic networks and social media platforms to reach a broader student population. A total of 115 valid responses were collected and utilized for the analysis. The online mode of data collection enabled efficient response gathering while maintaining respondent anonymity and encouraging honest behavioural reporting regarding streaming usage and study habits during examination periods.

3.2 SAMPLING METHOD AND PARTICIPANT DIVERSITY

The research employed a **Convenience Sampling** method, targeting students currently enrolled in active study across various educational levels. This approach was highly effective for gathering data from a demographic that is inherently invested in digital platforms. The sample includes respondents from diverse academic backgrounds, including those in Engineering, Commerce, Science, Humanities, and Law. Participants were drawn from several prominent institutions, including Takshashila University, SRM Institute of Science and Technology, Fatima College, and Kathir College of Engineering. This diversity ensures that the findings reflect a wide range of institutional pressures and academic cultures, from early secondary education to advanced postgraduate studies. The near-equal split between respondents who report study delay and those

who do not provides a balanced basis for econometric modelling.

3.3 RESEARCH QUESTIONNAIRE (PRIMARY RESEARCH TOOL)

The following questions were presented to 115 participants via the Google Form survey to gather the data utilized in this study:

1. **Age:** Under 18, 18–20, 21–23, 24+.

2. **Name of College or School.**

3. **Academic Department:** Engineering, Commerce, Science & Humanities, Law, etc.

Department
116 responses

4. **Year of Study:** 1st Year, 2nd Year, 3rd Year, Final Year, Postgraduate.

Year of Study
116 responses

5. **Streaming Frequency:** How often do you use streaming platforms (YouTube, Netflix, etc.)? (Occasionally, Few times a week, Daily).

How often do you use streaming platforms (YouTube, Netflix, etc.)?
118 responses

6. **Contextual Viewing:** Do you watch streaming content during exam preparation? (Never,

Rarely, Sometimes, Always).

Do you watch streaming content during exam preparation?

118 responses

7. **Daily Intensity:** On average, how much time do you spend on streaming per day during exams? (<1 hour, 1–2 hours, 2–3 hours, >3 hours).

On average, how much time do you spend on streaming per day during exams?

118 responses

8. **Procrastination Self-Report:** Do you delay your studies because of streaming? (Yes, No).

Do you delay your studies because of streaming?

118 responses

9. **Time Planning:** What is your planned break duration? (5–10 minutes, 10–20 minutes,

More than 20 minutes).

What is your planned break duration?

118 responses

10. **External Regulation:** If your parents take away your phone during exams, do you feel it helps you focus better on studies? (Yes, No).

If your parents take away your phone during exams, do you feel it helps you focus better on studies?

49 responses

11. **Break Extension:** After starting streaming, your actual break duration (Remains the same, Slightly increases, Increases significantly).

After starting streaming, your actual break duration

118 responses

12. Focus Improvement: Does streaming during breaks reduce or improve your focus?

Streaming during breaks

118 responses

13. Overwatching Tendency: After starting a video, how often do you end up watching more than you planned? (Never, Sometimes, Often, Always).

After starting a video, how often do you end up watching more than you planned?

117 responses

14. Subjective Rationale: Why do you think streaming affects your study behavior during exams? (Thematic open response).

3.4 DATA FIELDS AND OPERATIONALIZATION OF VARIABLES

The dataset is structured around five primary variables used in the econometric analysis. The dependent variable, Study Delay, is a binary indicator where 1 represents students experiencing study delay due to streaming activities and 0 represents students not experiencing study delay.

The independent variables include Age-Code, Streaming Frequency, Streaming Time, and Over-watching Behaviour. Age-Code was included to account for differences in maturity levels and academic responsibility across respondents. Streaming Frequency measures the regularity of streaming platform usage, while Streaming Time captures the intensity of daily viewing duration during examinations. Over-watching Behaviour measures the tendency of students to continue watching content beyond their planned viewing duration.

These coded variables enabled the application of Binary Logistic Regression techniques to identify the statistical relationship between streaming-related behavioural factors and students' academic delay during examination periods.

3.5 DESCRIPTIVE STATISTICS AND DATA INTEGRITY

Preliminary analysis of the one hundred fifteen records reveals a population deeply engaged in the digital leisure paradigm. The mean Age-Code of two point three nine indicates a primary demographic of late adolescents and young adults. The Frequency-Code mean of two point four nine suggests that daily streaming is a normalized behavior for the majority of the sample. Notably, the Overwatch-Code mean of two point seven one and median of three point zero confirmed that "often" watching more than planned is a prevalent habit. Correlation analysis shows that multicollinearity is not a significant concern, as coefficients between predictors remain low. The strongest associations with Study Delay were found in Overwatching (zero point two four eight) and Streaming Time (zero point two two six), providing initial quantitative evidence that viewing intensity is more detrimental to academic discipline than simple frequency.

CHAPTER 4

METHODOLOGY

4.1 INTEGRATED MIXED-METHODS WORKFLOW

The present study adopted a mixed-methods approach combining quantitative and qualitative analysis to examine the impact of streaming behaviour on students' study delay during examination periods. Primary data was collected through a structured Google Forms questionnaire distributed among students from different educational backgrounds. The collected responses were cleaned, coded, and prepared for analysis. The quantitative analysis was conducted using Python and included descriptive statistics, correlation analysis, and Binary Logistic Regression. Additional model validation techniques such as confusion matrix analysis, ROC-AUC analysis, classification report evaluation, and Variance Inflation Factor (VIF) diagnostics were performed to assess model reliability and predictive performance. The qualitative analysis involved thematic analysis of 69 open-ended responses to identify recurring behavioural patterns associated with streaming behaviour, including distraction, over-watching, time mismanagement, and academic procrastination. The combined use of quantitative and qualitative analysis provided a broader understanding of how streaming-related activities influence students' study discipline during examination periods.

4.2 SPECIFICATION OF THE ECONOMETRIC MODEL

Since the dependent variable of the study is binary in nature (Study Delay: Yes/No), Binary Logistic Regression (BLR) was selected as the appropriate econometric model for analysis. The model estimates the probability that a student experiences study delay based on streaming-related behavioural variables.

The Binary Logistic Regression model is specified as:

$$\log(P/1-P) = \beta_0 + \beta_1(\text{Age}) + \beta_2(\text{Overwatching}) + \beta_3(\text{Streaming Frequency}) + \beta_4(\text{Streaming Time})$$

Where:

- "P" represents the probability of study delay.
- β_0 represents the intercept term.
- $\beta_1, \beta_2, \beta_3$, and β_4 represent the coefficients of the explanatory variables.

The logistic regression model was preferred because it is suitable for predicting categorical outcomes and estimating the probability of behavioural events such as study delay.

4.3 DIAGNOSTICS AND MODEL VALIDATION

The performance of the Binary Logistic Regression model was evaluated using a confusion matrix and prediction accuracy measures. The confusion matrix compares the predicted classifications generated by the model with the actual observed responses in the dataset.

The model correctly classified 73 out of 115 observations, resulting in an overall prediction accuracy of approximately 63.5%. The findings indicate satisfactory predictive performance within the context of behavioural social science research.

The overall statistical significance of the model was further confirmed through the likelihood ratio test, which produced a p-value of 0.0086, indicating that the explanatory variables jointly contribute to explaining students' study delay behaviour during examination periods.

Additionally, diagnostic tests were conducted to evaluate the reliability and predictive performance of the Binary Logistic Regression model. Multicollinearity among explanatory variables was examined using the Variance Inflation Factor (VIF). The VIF values for all independent variables remained close to 1, indicating the absence of severe multicollinearity in the dataset. Further, model discrimination ability was assessed using the Receiver Operating Characteristic (ROC) Curve and Area Under the Curve (AUC) analysis. The model achieved an AUC score of 0.69, suggesting satisfactory classification performance in distinguishing students experiencing study delay from those not experiencing delay.

Table 1: Model Diagnostics

Metric	Value
Accuracy	63.5%
ROC-AUC	0.695
Precision	0.64
Recall	0.63
F1-score	0.63

4.4 SOFTWARE AND TOOLS USED

The quantitative analysis was conducted using Python programming language through Visual Studio Code (VS Code). Libraries including Pandas, Statsmodels, Scikit-learn, and Matplotlib were utilized for data processing, Binary Logistic Regression estimation, model validation, and data visualization. Microsoft Excel was additionally used for initial data cleaning, coding, and dataset preparation.

4.4 QUANTITATIVE ANALYSIS

The quantitative analysis of the study was conducted using descriptive statistics, correlation analysis, and Binary Logistic Regression techniques to examine the relationship between streaming behaviour and students' study delay during examination periods.

Initially, descriptive statistics were used to summarize the behavioural characteristics of the respondents, including streaming frequency, streaming duration, overwatching behaviour, and age distribution. Measures such as mean, median, and standard deviation were utilized to understand the overall behavioural patterns present within the dataset.

Further, correlation analysis was performed to examine the strength and direction of relationships between the independent variables and the dependent variable. The correlation results indicated that Overwatching Behaviour and Streaming Time showed relatively stronger positive associations with Study Delay compared to other behavioural variables. Since all correlation coefficients between independent variables remained below 0.8, severe multicollinearity was not observed in the dataset.

To estimate the probability of students experiencing study delay during examination periods, Binary Logistic Regression (BLR) was employed as the primary econometric model. The dependent variable of the study, Study Delay, was binary in nature, where:

- 1 = Students experiencing study delay due to streaming behaviour
- 0 = Students not experiencing study delay

The independent variables included:

- Age
- Streaming Frequency

- Streaming Time
- Overwatching Behaviour

The Binary Logistic Regression model was estimated using Maximum Likelihood Estimation (MLE) to identify the behavioural variables that significantly influence students' probability of delaying their studies during examination periods.

The model is represented as:

$$\log\left(\frac{P}{1-P}\right) = \beta_0 + \beta_1(Age) + \beta_2(Overwatching) + \beta_3(Streaming\ Frequency) + \beta_4(Streaming\ Time)$$

Where:

- P represents the probability of study delay.
- β_0 represents the intercept term.
- $\beta_1, \beta_2, \beta_3,$ and β_4 represent the coefficients of the explanatory variables.

The regression findings indicated that Streaming Time and Overwatching Behaviour were statistically significant predictors of study delay among students during examinations. The model achieved an overall classification accuracy of 63.5%, suggesting satisfactory predictive performance within the context of behavioural social science research.

4.5 QUALITATIVE ANALYSIS

In addition to the quantitative analysis, the study also incorporated qualitative analysis to obtain a deeper behavioural understanding of how streaming activities influence students' study discipline during examination periods.

The qualitative analysis was conducted using thematic analysis of open-ended responses collected through the survey questionnaire. Students were asked to explain how streaming behaviour affects their academic preparation and study consistency during exams. A total of 69 valid qualitative responses were analyzed.

The responses were carefully reviewed and grouped into recurring behavioural themes based on similarities in student experiences and perceptions. The major themes identified from the analysis included:

- Distraction and reduced focus
- Overwatching behaviour
- Time mismanagement
- Procrastination and study delay
- Loss of self-control during streaming sessions
- Reduced academic concentration during exams

A dominant behavioural pattern observed among respondents was the tendency for short study breaks to gradually transform into prolonged streaming sessions. Many students reported that “one episode turns into hours,” indicating loss of time control and difficulty disengaging from digital entertainment platforms during examination preparation.

Several respondents also stated that streaming platforms reduce concentration levels and interrupt planned study schedules, ultimately leading to ineffective time management and delayed academic preparation. In contrast, a smaller group of respondents viewed streaming as a temporary stress-relief mechanism that helped reduce examination anxiety.

Additionally, responses from school-level students suggested that parental supervision and restricted access to mobile phones during exams improved focus and reduced streaming-related distractions. This finding indicates that external behavioural regulation may positively influence students’ academic discipline during high-pressure examination periods.

Overall, the qualitative analysis supported and strengthened the quantitative findings by providing behavioural explanations for the statistically significant relationship between streaming behaviour and study delay among students.

CHAPTER 5

ANALYSIS AND RESULTS

5.1 ANALYSIS OF REGRESSION COEFFICIENTS

The Binary Logistic Regression results indicate that streaming-related behavioural variables significantly influence students' study delay during examination periods.

Variables with p-values less than 0.05 were considered statistically significant predictors of study delay.

The regression analysis identified Streaming Time and Overwatching Behaviour as statistically significant behavioural predictors affecting students' probability of delaying their studies

Table 2: Analysis of Regression Coefficients

Variable	Coefficient	Std. Error	P-Value
Constant	-2.922	1.167	0.012
Age	-0.031	0.240	0.897
Streaming Frequency	0.363	0.301	0.227
Streaming Time	0.384	0.195	0.049
Overwatching	0.490	0.209	0.019

5.2 INTERPRETATION OF THE "OVERWATCHING" EFFECT

Overwatching behaviour emerged as the strongest statistically significant behavioural predictor of study delay in the estimated model. The positive coefficient of zero point four nine zero indicates that as the tendency to continue watching beyond the planned time increases, so does the risk of academic procrastination. To provide a clearer interpretation, we calculate the odds ratio by

exponentiating the coefficient:

$$e^{0.490} = 1.63(\text{approx.})$$

This result demonstrates that for every one-unit increase in the Overwatching scale (for example, moving from "Often" to "Always"), the likelihood of a student experiencing study delay increases by approximately sixty-three percent. This statistical evidence reinforces the danger of the "just one more episode" mentality, proving that the lack of self-regulation during viewing sessions is the primary mechanism through which digital entertainment disrupts academic preparation.

Figure 2: Distribution of Students Experiencing Study Delay

5.3 CLASSIFICATION METRICS AND MODEL ROBUSTNESS

The confusion matrix (Image 1) serves as the final validation of the model's robustness. The True Negative count of 36 and True Positive count of 37 show that the model is effective at identifying both procrastinators and disciplined students. The overall accuracy of sixty-three point five percent is supplemented by a likelihood ratio test p-value of zero point zero zero eight six, which confirms that the combination of behavioral variables significantly explains the observed study delays. These results allow for the rejection of the null hypothesis that streaming habits have no effect on exam preparation, establishing a definitive and statistically significant link between intensive digital leisure and the postponement of academic tasks.

Figure 3: Confusion Matrix of Binary Logistic Regression Model

5.4 MULTICOLLINEARITY TEST (VIF ANALYSIS)

To ensure the reliability of the Binary Logistic Regression estimates, multicollinearity among the explanatory variables was tested using the Variance Inflation Factor (VIF). Multicollinearity occurs when independent variables are highly correlated with each other, which may distort regression estimates and reduce model reliability.

The VIF results indicated that all independent variables had values close to 1, suggesting the absence of severe multicollinearity within the dataset. Since all VIF values were substantially below the commonly accepted threshold value of 5, the explanatory variables were considered statistically independent and appropriate for inclusion in the regression model.

Table 3: VIF Analysis Table

Variable	VIF
Age	1.01
Streaming Frequency	1.04
Streaming Time	1.05
Over-watching Behaviour	1.02

The findings confirm that the regression coefficients obtained from the Binary Logistic Regression model are stable and not affected by excessive inter-variable correlation.

5.5 ROC CURVE AND MODEL PERFORMANCE

The predictive performance of the Binary Logistic Regression model was further evaluated using the Receiver Operating Characteristic (ROC) Curve and Area Under the Curve (AUC) analysis.

The ROC Curve measures the model's ability to correctly distinguish between students who experience study delay and those who do not.

The model achieved an AUC score of 0.695, indicating satisfactory classification ability within the context of behavioural social science research. Since the AUC value is substantially above 0.5, the model demonstrates better predictive performance than random classification.

The ROC analysis confirms that the selected behavioural variables — particularly streaming time and over-watching behaviour — provide meaningful predictive information regarding students'

likelihood of delaying their studies during examination periods.

Figure 3: ROC Curve

5.6 CLASSIFICATION REPORT

The classification report was used to evaluate the predictive quality of the Binary Logistic Regression model. Precision, recall, and F1-score values were calculated for both categories of the dependent variable.

Table 4: Classification Table

Category	Precision	Recall	F1-Score
No Study Delay (0)	0.62	0.64	0.63
Study Delay (1)	0.65	0.63	0.64

The classification results indicate balanced predictive performance across both categories, suggesting that the model performs reasonably well in identifying students who experience study delay as well as those who maintain academic discipline during examination periods.

CHAPTER 6

DATA VISUALIZATION AND RESULT INTERPRETATION

6.1 ANALYSIS OF DATA VISUALIZATIONS

This chapter presents the graphical representation and interpretation of the quantitative findings obtained from the Binary Logistic Regression analysis. The primary visualization used to assess model performance is the Confusion Matrix (Image 1), which illustrates the classification accuracy of the logistic model. The diagonal cells representing True Negatives (36) and True Positives (37) confirm that the model identifies both disciplined and procrastinating students with relatively equal precision. The presence of 20 False Positives and 22 False Negatives suggests a balanced error rate, indicating that the model does not suffer from categorical bias. This visualization is critical for confirming that the variables selected—Streaming Time and Overwatching—are statistically valid classifiers for academic delay.

6.2 INTERPRETATION OF BEHAVIORAL COEFFICIENT TRENDS

The behavioural coefficient visualization provides a comparative representation of the influence exerted by each explanatory variable within the Binary Logistic Regression model. Among the variables included in the analysis, Over-watching Behaviour recorded the highest positive coefficient value, followed by Streaming Time.

In contrast, Age and Streaming Frequency demonstrated relatively weaker effects and were statistically insignificant within the estimated model. The visualization indicates that over-watching behaviour and streaming time exert relatively stronger influence on students' study delay compared to age and streaming frequency.

These findings suggest that prolonged viewing duration and difficulty disengaging from streaming platforms are important behavioural factors associated with academic procrastination during examination periods.

Figure 4 : Logistic Regression Coefficient Plot

The below Logistic Regression probability curve illustrates the positive relationship between streaming time and the probability of study delay among students. The graph shows that as the amount of time spent on streaming increases, the predicted probability of students delaying their studies also increases. The upward trend of the curve supports the regression findings, where Streaming Time was identified as a statistically significant predictor of study delay. The visualization further indicates that prolonged streaming exposure may negatively affect students' academic time management during examination periods.

CHAPTER 7

CONCLUSION AND FUTURE ENHANCEMENT

7.1 SUMMARY AND CONCLUSION

This investigation establishes a statistically significant link between digital streaming behaviors and academic study delay. The intensity of consumption—specifically the duration of sessions and the inability to stop (overwatching)—is a far more potent driver of procrastination than the simple frequency of use. The econometric model successfully quantified this risk, showing that overwatching behavior increases the odds of study delay by 63% and achieving a predictive accuracy of 63.5%. Qualitative findings reinforced these results, identifying distraction and loss of control as the primary psychological mechanisms of delay. While OTT platforms provide value as a stress-relief tool, their excessive and uncontrolled usage may negatively affect students' academic discipline and study consistency.

7.2 RECOMMENDATIONS FOR INSTITUTIONAL POLICY

Based on the evidence, educational institutions should consider several strategies to mitigate digital procrastination. First, examination scheduling should be revised to avoid excessively long periods that lead to cognitive fatigue and increased escapism. A shift toward multiple lower-stakes assessments can reduce the peak stress that drives students to engage in extended streaming. Second, schools and universities should integrate digital wellness programs into their curricula. These programs should focus on building digital resilience, teaching students to recognize the triggers of overwatching, and encouraging the use of self-regulation tools like session timers.

7.3 LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

While the findings of this study are significant, several limitations provide opportunities for future research. The analysis is based on self-reported survey responses, which may involve social desirability bias. Future studies should utilize longitudinal designs to track how streaming habits change over the course of an entire academic year and incorporate actual academic performance data (GPA) to measure the long-term impact on success. Additionally, exploring the specific discrepancy between planned break duration and actual viewing time during high-pressure academic intervals would provide more granular insights into time control failure.
